

Data Structures

3. Arrays ADT and C++ Implementation

Arrays

- An array is defined as
 - Ordered collection of a fixed number of elements
 - All elements are of the same data type
- Basic operations
 - Direct access to each element in the array
 - Values can be retrieved or stored in each element

C/C++ Implementation of an Array ADT

As an ADT	In C/C++
Ordered	Index: 0,1,2, ... SIZE-1
Fixed Size	intExp is constant
Homogeneous	dataType is the type of all elements
Direct Access	Array subscripting operator []

Properties of an Array

- **Ordered**
 - Every element has a well-defined position
 - First element, second element, etc.
- **Fixed size or capacity**
 - Total number of elements are fixed
- **Homogeneous**
 - Elements must be of the same data type (and size)
 - Use arrays only for homogeneous data sets
- **Direct access**
 - Elements are accessed directly by their position
 - Time to access each element is same
 - **Different to sequential access** where an element is only accessed after the preceding elements

Recap: Declaring Arrays in C/C++

```
dataType arrayName[intExp];
```

- datatype – Any data type, e.g., integer, character, etc.
- arrayName – Name of array using any valid identifier
- intExp – **Constant** expression that evaluates to a positive integer

- Example:

- `const int SIZE = 10;`
 - `int list[SIZE];`

Why constant?

- Compiler **reserves a block of consecutive memory locations** enough to hold SIZE values of type int

Recap: Accessing Arrays in C/C++

`arrayName[indexExp];`

- `indexExp` – called **index**, is any expression that evaluates to a positive integer
- In C/C++
 - Array index starts at 0
 - Elements of array are indexed 0, 1, 2, ..., SIZE-1
 - `[ ]` is called array subscripting operator
- Example
 - `int value = list[2];`
 - `list[0] = value + 2;`

list[0]	7
list[1]	
list[2]	5
list[3]	
	⋮
list[9]	

Array Initialization in C/C++ (1)

```
dataType arrayName[intExp]= {list of values}
```

- In C/C++, arrays can be **initialized at declaration**
 - intExp is **optional**: Not necessary to specify the size
- Example: Numeric arrays
 - `double score[ ] = {0.11, 0.13, 0.16, 0.18, 0.21}`

	0	1	2	3	4
score	0.11	0.13	0.16	0.18	0.21

- Example: Character arrays
 - `char vowel [5] = { 'A', 'E', 'I', 'O', 'U' }`

	0	1	2	3	4
vowel	A	E	I	O	U

Array Initialization in C/C++ (2)

- Fewer values are specified than the declared size of an array
 - Numeric arrays: Remaining elements are assigned zero
 - Character arrays: Remaining elements contains null character '\0'
 - ASCII code of '\0' is zero

- Example

- ```
- double score[5] = {0.11, 0.13, 0.16}
```

|       |      |      |      |   |   |
|-------|------|------|------|---|---|
| score | 0.11 | 0.13 | 0.16 | 0 | 0 |
|-------|------|------|------|---|---|

- ```
- char name[6] = { 'J', 'O', 'H', 'N' }
```

name	J	O	H	N	\0	\0
------	---	---	---	---	----	----

- If **more values** are specified than declared size of an array
 - **Error** is occurred: Handling depends on compiler

Array Addressing (1)

- Consider an **array declaration**: `int list [4] = { 1, 2, 4, 5 }`
 - Compiler allocates a **block of four memory spaces**
 - Each memory space is large enough to **store an int value**
 - Four memory spaces are **contiguous**
- **Base address**
 - Address of the first byte (or word) in the contiguous block of memory
 - Address of the memory location of the first array element
 - Address of element `list[0]`
- Memory address associated with `arrayName` **stores the base address**
- **Example**
 - `cout << list << endl;` (Print 1000)
 - `cout << *list << endl;` (Print 1)
- `*` is **dereferencing operator**
 - Returns content of a memory location

Array Addressing (2)

- Consider a statement: `cout << list[3];`
 - Requires array reference `list[3]` be **translated into memory address**
 - **Offset**: Determines the address of a particular element w.r.t. base address
- Translation
 - Base address + offset = $1000 + 3 \times \text{sizeof}(\text{int}) = 1012$
 - Content of address 1012 are retrieved & displayed
- An **address translation** is carried out each time an array **element is accessed**
- What will be printed and why?
 - `cout << *(list+3) << endl;`

Questions

- Why does an array index start at zero?
- Why arrays are not passed by value?

Multidimensional Arrays

- Most languages support arrays with more than one dimension
 - High dimensions capture characteristics/correlations associated with data
- **Example:** A table of test scores for different students on several tests
 - 2D array is suitable for storage and processing of data

	Test 1	Test 2	Test 3	Test 4
Student 1	99.0	93.5	89.0	91.0
Student 2	66.0	68.0	84.5	82.0
Student 3	88.5	78.5	70.0	65.0
⋮	⋮	⋮	⋮	⋮
⋮	⋮	⋮	⋮	⋮
Student N	100.0	99.5	100.0	99.0

Two Dimensional Arrays – Declaration

```
dataType  arrayName[intExp1][intExp2];
```

- intExp1 – constant expression specifying number of rows
 - intExp2 – constant expression specifying number of columns
-
- Example:
 - const int NUM_ROW = 2, NUM_COLUMN = 4;
 - double scoreTable [NUM_ROW][NUM_COLUMN];
-
- Initialization:
 - Double scoreTable [][4] = { {0.5, 0.6, 0.3},
 {0.6, 0.3, 0.8}};
 - List the initial values in braces, row by row
 - May use internal braces for each row to improve readability

Two Dimensional Arrays – Processing

```
arrayName[indexExp1][indexExp2];
```

- indexExp1 – row index
- indexExp2 – column index
- Rows and columns are numbered from 0
- Use nested loops to vary two indices
 - Row-wise or column-wise manner
- Example
 - `double value = score[2][1];`
 - `score[0][3] = value + 2.0;`

score	[0]	[1]	[2]	[3]
[0]				2.7
[1]				
[2]		0.7		
[3]				
	⋮	⋮	⋮	⋮
[9]				

Higher Dimensional Arrays

- **Example:** Store and process a table of test scores
 - For several different students
 - On several different tests
 - Belonging to different semesters

```
const int SEMS = 10, STUDENTS = 30, TESTS = 4;  
typedef double ThreeDimArray[SEMS][STUDENTS][TESTS];  
ThreeDimArray gradeBook;
```

- What is represented by `gradebook[4][2][3]`?
 - Score of 3rd student belonging to 5th semester on 4th test
- All indices start from zero

Array of Arrays (1)

- Consider the declaration
 - `double score[10][4];`
- Another way of declaration
 - One-dimensional (1D) array of rows

```
typedef double RowOfTable[4];  
RowOfTable score[10];
```

- In detail
 - Declare `score` as 1D array containing 10 elements
 - Each of 10 elements is 1D array of 4 real numbers (i.e., double)

score	[0]	[1]	[2]	[3]
[0]				
[1]				
[2]				
[3]				
	⋮	⋮	⋮	⋮
[9]				

score	[0]	[1]	[2]	[3]
[0]				
[1]				
[2]				
[3]				
	⋮	⋮	⋮	⋮
[9]				

Array of Arrays (2)

- `Score[i]`
 - Indicates i^{th} row of the table
- `Score[i][j]`
 - Can be thought of as `(score[i])[j]`
 - Indicates j^{th} element of `score[i]`

Generalization:

An n -dimensional array can be viewed (recursively) as a 1D array whose elements are $(n-1)$ -dimensional arrays

Array of Arrays – Address Translation

- How to access the value of `score[5][3]`?
- Suppose **base address** of `score` is `0x12348`
- Address of 5th element of `score` array, i.e., `score[5]`
 - $0x12348 + 5 \times \text{sizeof}(\text{RowOfTable}) = 0x12348 + 5 \times (4 \times 8)$
 $= 0x12488$
- Address of `score[5][3]`
 - Address of `score[5]` + $3 \times \text{sizeof}(\text{double}) = 0x12488 + 3 \times 8$
 $= 0x124a0$

```
typedef double RowOfTable[4];  
RowOfTable score[10]
```

Implementing Multidimensional Arrays

- More complicated than one dimensional arrays
- **Memory** is organized as a **sequence of** memory **locations**
 - One-dimensional (1D) organization
- How to use a 1D organization to store multidimensional data?

- Example:

A	B	C	D
E	F	G	H
I	J	K	L

- A character requires single byte
- Compiler request to reserve 12 consecutive bytes
- Two way to store consecutively, i.e., **row-wise** and **column-wise**

Two-dimensional Arrays in Memory

- Two ways to be represented in memory
 - Column majored
 - Column by column
 - Row majored
 - Row by row
 - Representation depends upon the programming language

	(1,1)	
	(2,1)	Column 1
	(3,1)	
	(1,2)	
	(2,2)	Column 2
	(3,2)	
	(1,3)	
	(2,3)	Column 3
	(3,3)	
	(1,4)	
	(2,4)	Column 4
	(3,4)	

	(1,1)	Row 1
	(1,2)	
	(1,3)	
	(1,4)	
	(2,1)	Row 2
	(2,2)	
	(2,3)	
	(2,4)	
	(3,1)	Row 3
	(3,2)	
	(3,3)	
	(3,4)	

Any Question So Far?

Array of Arrays

- Consider declaration: `double score[9][4];`
- Another way of declaration
 - One-dimensional (1D) array of rows
 - Declare score as 1D array containing 09 elements
 - Each of 30 elements is a 1D array of 4 real numbers (i.e., double)

```
typedef double RowOfTable[4];  
RowOfTable scoreTable[30]
```

score	[0]	[1]	[2]	[3]
[0]				
[1]				
[2]				
[3]				
	⋮	⋮	⋮	⋮
[9]				

score	[0]	[1]	[2]	[3]
[0]				
[1]				
[2]				
[3]				
	⋮	⋮	⋮	⋮
[9]				

- **Declaration**

- `datatype = arrayName [intExp1] [intExp2]`
- `intExp1` – constant expression specifying number of rows
- `intExp2` – constant expression specifying number of columns

- **Example:**

- `Int NUM_ROWS = 30, NUM_COLUMN = 4;`
- `double scoreTable[NUM_ROWS][NUM_COLUMN]`

- **Initialization**

Array Addressing (2)

- Consider a statement: `cout << list[3];`
 - Requires array reference `list[3]` be translated into memory address
 - **Offset:** Determines the address of a particular element w.r.t. base address
- Translation
 - Base address + 3 x `sizeof(int)` = 1012
 - Content of address 1012 are retrieved and displayed
- An address translation is

Array Addressing

- Consider an **array declaration**: `int list [4]`
 - Compiler allocates a **block of four memory spaces**
 - Each memory space is large enough to **store an `int` value**
 - Five memory spaces are **contiguous**
- **Base address**
 - Address of the first byte (or word) in the contiguous block of memory
 - Address of the memory location of the first array element
 - Address of element `list[0]`
- Memory address associated with `arrayName` **stores the base address**
- **Example**
 - `cout << list << endl;`
 - `cout << *list << endl;`
- `*` is **dereferencing operator**
 - Returns content of a memory location

Array Addressing

- Consider an **array declaration**: `int list [5]`
 - Compiler allocates a **block of five memory spaces**
 - Each memory space is large enough to **store an `int` value**
 - Five memory spaces are **contiguous**
- **Base address**
 - Address of the first byte (or word) in the contiguous block of memory
 - Address of the memory location of the first array element
 - Address of element `list[0]`
- **Offset**
 - Determines the address of a particular element w.r.t. base address

Array Initialization

```
dataType arrayName[intExp]= {list of values}
```

- In C/C++, arrays can be **initialized at declaration**
 - `intExp` is **optional**: Not necessary to specify the size
- **Example**
 - `double rate[ ] = {0.11, 0.13, 0.16, 0.18, 0.21}`
 - `double score[5] = {0.11, 0.13, 0.16}`

	0	1	2	3	4
score	0.11	0.13	0.16	0	0

- If **fewer values** are specified than declared size of an array
 - Remaining elements are **assigned zero**
- If **more values** are specified than declared size of an array
 - **Error** is occurred: Handling depends on compiler
